## ACKNOWLEDGEMENTS

The author received broad assistance in the generation of this report from a number of contributors. Listed by organization, those involved include the following:

### **Town of Cary**

Emily Barrett  
Melanie Bissonnette  
Ray Boylston  
Kelvin Creech  
Larry Dempsey  
Chris Duty  
Kyle Hubert  
Cecil Martin  
Chris Parisher  
Trish Terreault  
Juan Vega

### **UNC Institute for the Environment**

Dr. David McNelis, Ph.D.  
Tony Reevy  
Dr. Elizabeth Shay, Ph.D.  
Dr. Jason West, Ph.D.

### **Progress Energy**

Pat Newton  
Chante Woodard

### **Wake County Schools**

Lib McGowan

The Institute for the Environment at the University of North Carolina at Chapel Hill performed this work as part of its distinguished tradition of environmental research and service to communities in North Carolina and around the country.

Emily Barrett, Sustainability Manager at the Town of Cary and the Town Project Manager, provided exceptional assistance throughout this endeavor.

Special acknowledgment must be given to Melanie Bissonnette at Accounts Payable in the Town of Cary Finance Department. Her knowledge, reliability, and alacrity in assistance were invaluable throughout the lengthy process of data acquisition.

Dr. David McNelis, an energy expert, professor and researcher from the Institute for the Environment, lent his support for this project from the day it was conceptualized. His contribution has been much appreciated.

## EXECUTIVE SUMMARY

The Town of Cary has the opportunity to save thousands of dollars in municipal energy costs, and this energy and greenhouse gas inventory is the first step toward achieving savings. This report was commissioned by the Town of Cary's Sustainability Manager, Emily Barrett, and funded by the Energy Efficiency and Conservation Block Grant Program (EECBG) of the American Recovery and Reinvestment Act of 2009 (ARRA).

Goals of the EECBG program include:

- reducing fossil fuel emissions and energy use,
- improving energy efficiency, and
- creating and retaining jobs (DOE, 2009).

This report works toward these goals by conducting a detailed inventory of all energy use and greenhouse gas (GHG) emissions resulting from the municipal operations of the Town of Cary. Standard GHG calculation and reporting protocols for local government operations were followed to create this inventory.

Results of this report include the following:

- From 2005 to 2010, municipal energy costs amounted to \$43.9 million
- Annual energy costs increased from \$5.4 million in 2005 to \$8.3 million in 2010 (Figure 1)
- Annual energy costs amounted to an average of \$7,206 per employee in 2010, up from \$5,237 per employee in 2005
- On-site energy use has increased an average of 8% annually since 2005
- GHG emissions were 43,932 metric tonnes of carbon dioxide equivalent in 2010

Figure 1: Total Energy Costs, 2005-2010

- GHG emissions have increased an average of 5% annually since 2005
- GHG emissions have risen in every activity sector since 2005 (Figure 2)
- Water and wastewater treatment and delivery represent over 50% of energy use and over 60% of GHG emissions
- Emissions from fleet vehicles have more than doubled since 2005 due to a reported increase in the number of vehicles and equipment, from 333 in 2005 to 681 in 2010

As the adage says, “You cannot manage what you do not measure.” Detailed measurement of energy use provided by this inventory is the essential first step in developing an energy management program and strategic energy plan to reduce energy consumption and save money.

From the analysis, the following next steps are recommended for the Town of Cary:

1. Begin an energy management program
2. Create a strategic energy plan
3. Implement a fleet vehicle efficiency policy to guide new vehicle purchases
4. Promote energy literacy throughout the Town

Figure 2: Total GHG Emissions by Activity Sector, 2005-2010

# 1. INTRODUCTION

This report opens with a description of the general relationship between energy, fossil fuels, and greenhouse gases and establishes a basis for the relevancy of greenhouse gas (GHG) inventories. From there this chapter proceeds to list several ways GHG inventories are valuable before exploring in more detail GHGs and GHG accounting techniques.

## *Energy, Fossil Fuels, and Greenhouse Gases*

The Town consumes energy in a variety of ways. Electricity keeps the lights on; natural gas heats the buildings; and gasoline and diesel power the vehicle fleet. These energy sources have not changed much through the decades. According to the most recent annual report by the U.S. Energy Information Agency (EIA), over 86% of the world's energy needs are met by burning fossil fuels (EIA, 2008). Petroleum tops the list by providing 35.9% of the world's energy, followed by coal (27.4%) and natural gas (22.8%). As world population increases and modernization and electrification expand, the worldwide demand for energy continues to soar. No one can be certain of the size of remaining fossil fuel deposits, but it is true that these fuels are becoming more difficult and expensive to access. Political instability and nationalization of foreign oil wells hinder supplies. Concern about the long-term supply of coal is surfacing in many places around the world. Increasingly more involved and extractive measures such as mountaintop removal, deepwater oil drilling, and shale oil extraction are among acquisition methods adopted recently. These emerging energy trends make managing energy use more relevant than ever.

With 86% of the world's energy derived from fossil fuels, there is a significant amount of fossil fuel combustion occurring across the globe. When fossil fuels are burned, energy (in the form of heat) becomes the desired product, but carbon dioxide is a noteworthy byproduct. Carbon dioxide is a greenhouse gas (GHG), and it traps heat in the atmosphere. (Appendix A describes the effects carbon dioxide and other GHGs have on the earth's climate.) As the world is becoming more concerned about GHG emissions from anthropogenic sources, GHG emission tracking and "carbon footprints" are becoming common and even mandated in places. The main component of GHG accounting involves inventorying all energy consumption and calculating the resulting GHG emissions based on the carbon intensities of each fuel source. As discussed above fossil fuels are the primary sources of energy, but they are becoming more expensive and have become subject to erratic price fluctuations from outside stimuli (Middle East turmoil, hurricanes, market speculation, etc.). On the contrary many renewable energy sources are not subject to the same degree of volatility, and as an added benefit, their use emits either no or low anthropogenic GHGs. Thus, GHG accounting is also a method for energy consumers to measure and understand their reliance on energy from increasingly vulnerable sources (i.e. fossil fuels). In many ways this greenhouse gas inventory could very well be considered an "Energy Risk Assessment Inventory." Over time, the Town can utilize its GHG inventory to track its progress in migrating away from fossil fuels and foreign oil supplies and toward the price stability and national energy independence potentially offered by renewable energy sources.

## ***Value of GHG Emissions Inventories***

Considering that conducting a detailed energy inventory is the core of a GHG emissions inventory, there are a plethora of managerial benefits that spill over from the creation of a GHG inventory. Oftentimes, and as in the case of Cary, energy bills are simply budgeted for and paid by finance departments without much further analysis or oversight. Many organizations do not have an energy management strategy that can be used to assess current energy performance, identify opportunities for energy savings, and implement steps towards energy and cost reductions. The measurement of current energy use by the way of this inventory is the first step towards management improvements.

Additional benefits to local governments for performing a GHG inventory include:

1. Providing stakeholder education to management, constituents, and the public
2. Preparing for a carbon constrained future by identifying emission sources so a local government knows the implications of potential regulations
3. Managing risk by documenting early actions to reduce GHG emissions if future regulation is implemented
4. Being recognized as an environmental leader in the region (ICLEI, 2010).

## ***GHG Accounting Details***

GHG inventorying continues to be voluntary in most states including North Carolina, but the Environmental Protection Agency (EPA) was ordered to begin regulating GHGs by the U.S. Supreme Court in *Massachusetts v. EPA (2007)*. Even before the ruling, the state of California mandated that all municipalities report GHG emissions on an annual basis. ICLEI—Local Governments for Sustainability, a membership organization of municipalities committed to environmental stewardship, has provided technical assistance to municipalities to assist in mandatory and voluntary GHG reporting. ICLEI has partnered with the California Air Resources Board, California Climate Action Registry, and The Climate Registry to develop a protocol specifically intended for use by municipal governments called *Local Government Operations Protocol, for the quantification and reporting of greenhouse gas emissions inventories, Version 1.1*. The Town elected to utilize this extensive protocol as its standard. All decisions and calculations within this inventory have been made with the guidance provided by this protocol. For more details on the methodology of using this protocol and how it relates to the content of this inventory, see Appendix B. For emissions factors used to derive the results of this report, see the ICLEI protocol available online.

When accounting for GHG emissions, there are two classes of emissions that municipalities can be concerned with: 1) emissions from municipal operations and 2) emissions from the community as a whole. This inventory provides a detailed account of all GHG emissions associated with the municipal operations from the Town (see Appendix B for a list of these activities) and not the wider community. Energy use and emissions from municipal operations are much easier to accurately measure and effectively intervene; thus, these are the primary concern of the Town at this time.

This inventory reports results on the six internationally recognized greenhouse gases regulated under the Kyoto Protocol. Three are naturally occurring and three are synthetic fluorinated gases:

- Carbon dioxide (CO<sub>2</sub>)
- Methane (CH<sub>4</sub>)
- Nitrous oxide (N<sub>2</sub>O)
- Hydrofluorocarbons (HFCs)
- Perfluorocarbons (PFCs)
- Sulfur hexafluoride (SF<sub>6</sub>)

Carbon dioxide is the most prevalent of the six greenhouse gases recognized by the Kyoto Protocol. It is formed during all hydrocarbon combustion reactions, which include all fossil fuels. Carbon dioxide results from combustion of gasoline, diesel, natural gas, propane, and coal, each of which are pertinent to the Town's operations.

Within municipal operations methane is emitted from solid waste in landfills and wastewater treatment when anaerobic conditions occur. Methane is also produced in trace amounts in all combustion reactions of fossil fuels. Within municipal operations at the Town of Cary, methane results only in trace amounts from combustion activities.

Nitrous oxide is emitted through the nitrification and denitrification processes of wastewater treatment, from wastewater effluent, by application of fertilizers, and during agricultural soil management practices. Like methane, it is also produced in trace amounts in all combustion reactions of fossil fuels.

The synthetic chemicals used within municipal operations are primarily HFCs as refrigerants in air conditioning and refrigeration systems. PFCs are utilized in industrial processes, and SF<sub>6</sub> is used during electrical transmission and distribution as well as magnesium production. Fugitive emissions result when these synthetic greenhouse gases escape from their intended use during installation leakage, normal operational leakage, and system failures. Even though low volumes are typically emitted, the high global warming potential of these gases can make for substantial emissions equivalents.

Greenhouse gas emissions should not be confused with air pollution from criteria air pollutants. Criteria air pollutants, including nitrogen oxides (NO<sub>x</sub>), sulfur dioxide, carbon monoxide, ozone, and particulate matter cause acute respiratory illness, smog, acid rain, and other environmental woes. Carbon dioxide and nitrous oxide are inert and pose no direct respiratory or health risks. Methane is not a criteria air pollutant but has been shown to catalyze the formation of ozone.

Each of the greenhouse gases has unique properties and affects global warming to various extents. For instance, methane is 21 times more potent in terms of global warming potential than carbon dioxide over the course of 100 years. In other words, one kilogram of methane gas traps the equivalent amount of atmospheric heat as 21 kilograms of carbon dioxide. Even worse, nitrous oxide traps 310 times as much heat as carbon dioxide, and some of the synthetic chemicals are up to 23,000 times as strong as carbon dioxide. In order to create a meaningful expression of the total emissions of the six greenhouse gases, the measurement standard of "carbon dioxide equivalents" is used. Quantities of non-carbon dioxide GHG emissions are weighted by their global warming potential and are

expressed using the conventional GHG reporting standard of metric tonnes of carbon dioxide equivalents (MTCDE). Greenhouse gas accounting utilizes the metric system to establish international continuity in emissions reporting.

Carbon dioxide emissions are calculated by using standard emissions factors corresponding to the relative carbon content of each fuel type. For example, no matter what type of vehicle a gallon of gasoline is combusted in, 8.78 kilogram (kg) of carbon dioxide will result due to the inherent carbon content of gasoline. This figure is 10.21 kg of carbon dioxide for a gallon of diesel. Similar factors exist for natural gas and propane combustion. In the case of electricity, energy is being converted off-site from a raw to a refined form from a fuel resource mix that is not readily known. Because of the interconnectedness of the electrical grid, it is impossible to determine the exact raw energy source used to generate a given kilowatt-hour (kWh) of electricity. The EPA does, however, publish the Emissions and Generation Resource Integrated Database (eGRID) that supplies regional and statewide averages of both emissions and resource mixes. For instance, the most recent update lists North Carolina as generating 61% of its electricity from coal, 31% from nuclear, 3% from natural gas, 2% from hydro and the balance from other sources (EPA, eGRID, 2010). This database also yields emissions rates for carbon dioxide, methane, nitrous oxide, and NO<sub>x</sub> on a pound-mass per megawatt-hour basis (lb/MWh). Per the ICLEI protocol, the “SRVC” Virginia/Carolinas subregion emission factors are utilized from eGRID2007 for years 2005 and 2006 and eGRID2010 for 2007 to present.

Carbon dioxide is emitted from all combustion reactions, even those of biofuels such as biodiesel, ethanol, wood, and methane collected from biomass. Because these fuels are derived from biological matter that is found within the earth’s natural carbon cycle, such as trees and plants, the carbon dioxide emitted from biofuels is biogenic in origin and thus does not contribute to anthropogenic GHG accumulation. Biogenic emissions from biodiesel use do not count as part of the total greenhouse gas emissions for town activities and have been reported separately as an information item. Trace methane and nitrous oxide from the combustion of biofuels is still reported as an anthropogenic GHG source because these trace emissions resulted from combustion, a human activity. The biogenic carbon, however, would have eventually become gaseous carbon dioxide through natural decomposition processes.

In 2010 the Town of Cary emitted 43,932 MTCDE of GHGs from its municipal operations. To put this number into context, these greenhouse gases are equivalent to those that result from average electricity use in 6,385 homes in North Carolina over the course of one year<sup>1</sup> or 7,988 average cars in operation for one year<sup>2</sup>. In order to sequester this quantity of greenhouse gases each year, a 68.6-square-mile forest of southern pines would need to be planted and properly managed (Birdsey, 1996). This area is larger than the Town of Cary’s area of 54.0 square miles (OSBM, 2010). Though facts like these can help explain the magnitude of the Town’s emissions, the most important aspect of GHG management is to understand current emissions trends and identify opportunities for savings.

---

<sup>1</sup> North Carolina average: 13,488 kWh or 6.9 MTCDE per house per year (EIA, 2010)

<sup>2</sup> National average: 5.5 MTCDE per passenger vehicle per year (EPA, 2005)

## 2. WEATHER STATISTICS OVER STUDY PERIOD

Since inventories build upon one another from year-to-year and allow comparisons to be made across time, it is important to include information that may impact the integrity of the data each year. Changes happen – operations can be outsourced, data can be mistakenly omitted, and weather can lead to significant changes in annual energy use. Weather correction or normalization is not a component of GHG accounting, but it can provide some explanation for unusual activity.

Heating degree days (HDD) are measured as the difference between the average temperature of each day and a base temperature (65 degrees in most cases) when the average temperature is below the base temperature. Cooling degree days (CDD) are measured in the same way except when the average temperature is above the base temperature. Daily values are summed across the entire year, and the result yields an understanding of roughly how much heating and cooling is needed at a given location during a given year.

The average HDD from 1971 to 2000 was 3,402 as recorded at the Raleigh-Durham International Airport (RDU) by the National Oceanic and Atmospheric Administration (NOAA). Asheville, North Carolina has an annual average of about 4,200; Anchorage, Alaska is 10,470; Miami, Florida is 150. The average CDD from 1971 to 2000 at RDU was 1,560. Asheville has a CDD average of 850; Anchorage is 3; Miami is 4,380 (NOAA, 2001).

Figure 3 indicates that the cold months of calendar year 2009 were slightly warmer than average and calendar year 2010 was the first colder than average year in the last ten years. From this, an increase in the use of heating fuels can be expected in 2010. If possible, selecting a baseline year with near average conditions provides the Town with more complete understanding on the effects of weather and GHG emissions.

Figure 3: Heating and Cooling Degree Days, 2001-2010

### 3. RESULTS AND ANALYSIS

Now that this report has introduced GHGs and some details of GHG accounting, this chapter contains a technical presentation of the energy and greenhouse gas inventory results for the Town of Cary. Tables and charts accompany concise explanations of the data and the trends. Data compiled from 2005 through 2010 are presented as annual totals by calendar year as reporting standards call for organizing results by calendar year. Cary has the opportunity to choose which year to distinguish as their baseline, against which to set reduction targets and compare future inventories. At times, this report presents tracked changes since 2005 only to showcase activity trends within all available data.

#### *Energy Use in Overall Municipal Operations*

As Table 1 demonstrates, the total cost of energy use among municipal operations has been rising steadily since 2005, reaching \$8.3 million in 2010. This figure includes an almost \$3 million leap in annual energy expenditures from 2005 to 2010. Electricity costs account for nearly \$2 million of that increase over the six-year period. Figure 4 demonstrates this rise and the relative share of each source graphically.

**Table 1**

**Total Energy Costs**

| By Source    | 2005               | 2006               | 2007               | 2008               | 2009               | 2010               |
|--------------|--------------------|--------------------|--------------------|--------------------|--------------------|--------------------|
| Electricity  | \$4,587,478        | \$5,072,279        | \$5,538,615        | \$5,857,827        | \$6,493,483        | \$6,555,339        |
| Natural Gas  | \$180,107          | \$594,993          | \$526,196          | \$628,548          | \$426,725          | \$433,387          |
| Propane      | \$31,752           | \$59,947           | \$63,751           | \$66,811           | \$62,652           | \$72,525           |
| Fleet Fuel   | \$631,710          | \$919,346          | \$1,048,516        | \$1,510,306        | \$1,323,534        | \$1,254,149        |
| <b>TOTAL</b> | <b>\$5,431,047</b> | <b>\$6,646,565</b> | <b>\$7,177,078</b> | <b>\$8,063,493</b> | <b>\$8,306,394</b> | <b>\$8,315,400</b> |

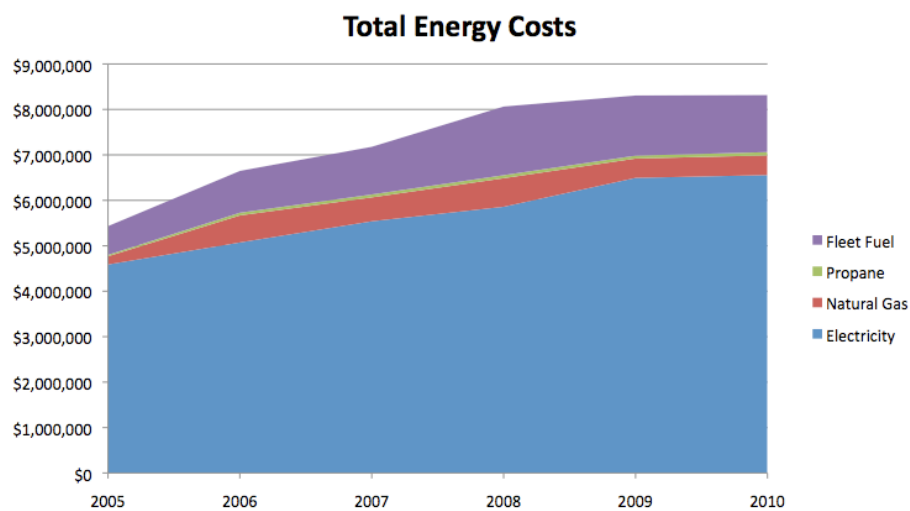

Figure 4: Total Energy Costs, 2005-2010

Evaluating total costs only tells the financial segment of the story. From this information alone, it cannot be determined whether costs are increasing because of rising energy prices, rising energy use, or both. Energy and GHG inventories take the extra step to analyze energy consumption and energy sources. Table 2 exhibits the total on-site energy use by each source, listed by its unique unit of measure.

**Table 2**  
**On-Site Energy Use**

| By Source     | Unit    | 2005       | 2006       | 2007       | 2008       | 2009       | 2010       |
|---------------|---------|------------|------------|------------|------------|------------|------------|
| Electricity   | kWhs    | 58,761,037 | 61,430,184 | 64,565,493 | 64,908,939 | 66,175,202 | 67,759,011 |
| Natural Gas   | therms  | 179,629    | 508,747    | 493,821    | 496,746    | 493,660    | 543,667    |
| Propane       | gallons | 10,269     | 20,958     | 23,231     | 20,661     | 21,012     | 23,506     |
| B20 Biodiesel | gallons | 150,053    | 211,212    | 252,013    | 290,219    | 335,559    | 366,456    |
| Gasoline      | gallons | 149,861    | 174,876    | 207,106    | 277,780    | 284,148    | 326,965    |

In order to gain a sense of how much total energy the Town uses, Table 3 expresses energy use in a unit of measure for energy, the British thermal unit (Btu). Results have been converted to million-Btus (MMBtu). Annual totals can now be compared to one another. Figure 5 demonstrates a trend similar to that of energy costs with just a few anomalies. Natural gas use has remained relatively constant though its cost has decreased, which is confirmed by the lower per unit prices currently in the natural gas market. Figure 5 shows fairly stable fleet fuel costs the last few years, but Figure 5 reveals that actual fleet fuel use has been growing. There have been lower per unit costs since the fuel price spike of 2008.

**Table 3**  
**On-Site Energy Use (MMBtu)**

| By Source    | 2005           | 2006           | 2007           | 2008           | 2009           | 2010           |

| <b>TOTAL</b> | <b>258,550</b> | <b>312,991</b> | <b>331,984</b> | <b>347,248</b> | <b>358,258</b> | <b>378,446</b> |

Figure 5: Total Energy Use, 2005-2010

Figure 6 and Table 4 show the Town's overall energy use profile across municipal operations. It is clear that the majority of on-site energy use in Cary is from electricity; however, as Table 5 demonstrates, fleet fuel has resulted in the most consistent year-to-year growth in energy consumption since 2005. Among natural gas use, the significant increase from 2005 to 2006 is explained by the opening of the biosolids dryer at the South Cary Water Reclamation Plant as 2006 was its first full year of operation. Increased natural gas and propane use in 2010 is likely due to a colder than average winter.

**Energy Use Profile in 2010**  
by Energy Source

Figure 6: Energy Use Profile by Source, 2010

**Table 4**  
**On-Site Energy Use Share (% of Total)**

| Share By Source | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|-----------------|------|------|------|------|------|------|
| Electricity     | 78%  | 67%  | 66%  | 64%  | 63%  | 61%  |
| Natural Gas     | 7%   | 16%  | 15%  | 14%  | 14%  | 14%  |
| Propane         | 0%   | 1%   | 1%   | 1%   | 1%   | 1%   |
| Fleet Fuel      | 15%  | 16%  | 18%  | 21%  | 23%  | 24%  |

**Table 5**  
**Year-to-Year Change in On-Site Energy Use (%)**

| By Source   | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|-------------|------|------|------|------|------|------|
| Electricity | -    | 5%   | 5%   | 1%   | 2%   | 2%   |
| Natural Gas | -    | 183% | -3%  | 1%   | -1%  | 10%  |
| Propane     | -    | 104% | 11%  | -11% | 2%   | 12%  |
| Fleet Fuel  | -    | 29%  | 19%  | 23%  | 9%   | 12%  |

Electricity use occurs from nearly 300 unique accounts spread throughout the town and is served by Progress Energy (250+ accounts), Duke Energy (8 accounts), and the Town of Apex Utilities (5 accounts). As Figure 7 demonstrates, water and wastewater treatment processes, including treatment and delivery, used the majority of electricity. Outdoor

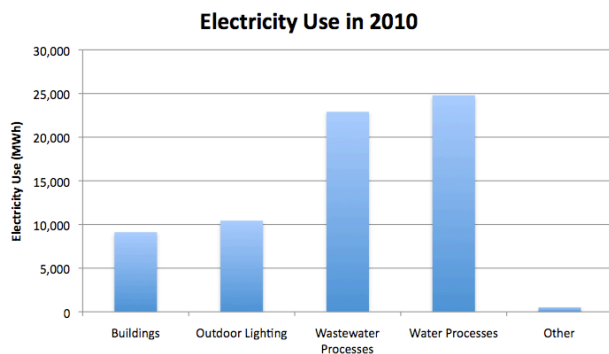

Figure 7: Emissions from Electricity by End Use, 2010

Figure 8: Natural Gas Use, 2010

lighting in the form of streetlights, sport lighting, parking lot lighting, and traffic-related signals and signs accounted for slightly over 10,000 megawatt-hours (MWh) of usage in 2010. Buildings used just under 10,000 MWh in 2010. Natural gas is used in 20 town buildings for space heating and/or domestic hot water. As Figure 8 shows, natural gas usage at the biosolids dryer at the South Cary Water Reclamation Plant represented 70% of all natural gas use in 2010. Propane use occurs primarily at the James Jackson complex that houses a number of operations from various divisions including Public Works and Utilities, Purchasing, and some Human Resources. Fleet fuel is consumed in the town vehicle fleet. Chapter 4 contains more information on the usage of fleet fuel

### ***GHG Emissions in Overall Municipal Operations***

Standard GHG emissions factors based on the carbon content of each fuel source are applied to energy data to calculate GHG emissions totals. Table 6 lists the GHG emissions by source.

**Table 6**  
**Total Greenhouse Gas Emissions (MTCDE)**

| By Source          | 2005          | 2006          | 2007          | 2008          | 2009          | 2010          |

| Annual Change      |               | 11.5%         | 4.4%          | 3.0%          | 2.6%          | 4.0%          |

Figure 9: Total GHG Emissions, 2005-2010

In addition to emissions from energy sources, greenhouse gases are also directly released from two non-combustion sources. Small amounts of nitrous oxide emissions escape during the nitrification and denitrification steps of wastewater treatment and also from the nitrogen content of the effluent. Those emissions comprise the “Wastewater Process” emissions. “HFC Fugitives” arise from direct hydrofluorocarbons that leak from refrigeration units. These escaping gases were estimated from the Fleet Division HFC purchase history for recharging air conditioning systems in town vehicles.

From 2005 to 2006, total emissions rose 11.5% due mainly to the opening of the biosolids dryer. Since then, total emissions have risen an average of 3.5% annually.

Table 7 and Figure 10 show the profile of emissions by source. Electricity is by far the largest source of emissions. Table 4 above established that electricity accounted for approximately 61% of the Town’s on-site energy use, while Table 7 demonstrates electricity accounts for 79% of all emissions. This emissions-energy ratio—79% of emissions to 61% of energy—demonstrates the high fossil fuel intensity of electricity compared to the other fuels used in town. If our state’s utility companies were to use less carbon-intensive fuel sources, this emissions-energy gap would not be as large.

**Table 7**  
**Emissions Share (% of Total)**

| By Source          | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|--------------------|------|------|------|------|------|------|
| Electricity        | 89%  | 83%  | 82%  | 80%  | 80%  | 79%  |
| Natural Gas        | 3%   | 7%   | 7%   | 6%   | 6%   | 7%   |
| Propane            | 0%   | 0%   | 0%   | 0%   | 0%   | 0.3% |
| Fleet              | 7%   | 9%   | 10%  | 12%  | 12%  | 13%  |
| Wastewater Process | 1%   | 1%   | 1%   | 1%   | 1%   | 1%   |
| HFC Fugitives      | 0%   | 0%   | 0%   | 0%   | 0%   | 0.1% |

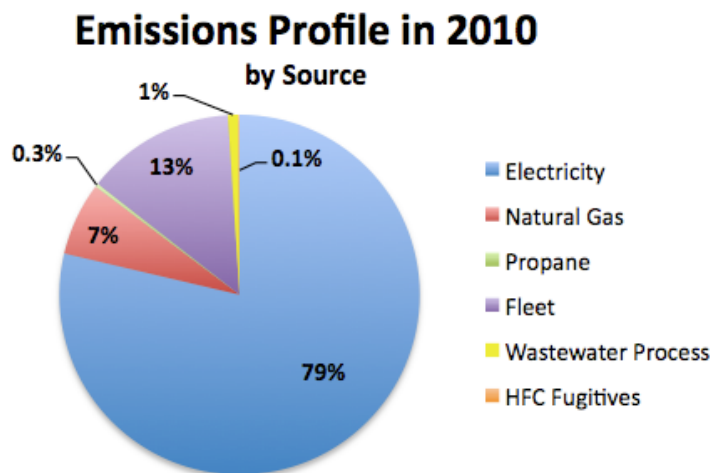

Figure 10: Emissions Profile by Source, 2010

Table 8 below reports overall emissions totals, listed by greenhouse gas in both total emissions rates in metric tonnes of each gas per year and in terms of MTCDE of each gas per year. Nitrogen oxides (NOx), though not a greenhouse gas, have been inventoried as well. See Chapter 6 for more details.

Because the fleet vehicles use a 20% biodiesel blend (“B20”) consisting of 20% diesel that has been produced from non-fossil fuel sources, there are additional carbon dioxide emissions that are not counted as part of the greenhouse gas emissions. These are identified as biogenic carbon dioxide emissions and are listed as an information item.

**Table 8**

**Emissions Totals**

| By Pollutant        | 2005   | 2006   | 2007   | 2008   | 2009   | 2010   |
|---------------------|--------|--------|--------|--------|--------|--------|
| CO2 (metric tonnes) | 33,801 | 37,700 | 39,381 | 40,489 | 41,543 | 43,254 |
| CH4 (metric tonnes) | 0.78   | 0.99   | 0.98   | 1.00   | 1.01   | 1.07   |

| MTCDE from N2O      | 536    | 570    | 577    | 600    | 617    | 605    |
| MTCDE from HFCs     | 0      | 0      | 0      | 51     | 63     | 50     |
| NOx (kg)            | 56,774 | 61,001 | 55,710 | 58,811 | 61,904 | 65,439 |
| Biogenic CO2 (MTs)  | 284    | 399    | 476    | 549    | 634    | 693    |

***Energy and Emissions by Activity Sector***

Energy use and GHG emissions have been subdivided by activity sector to yield a better understanding of the Town’s energy and emissions profile. The activity sectors selected that best correspond to the municipal operations of the Town of Cary include facilities, streetlights, fleet vehicles, water treatment and delivery (“water”), and wastewater treatment and processes (“wastewater”):

- Facilities -all buildings, parks and ballfields, lighting associated with those facilities, and leased spaces such as Middle Creek Community Center.
- Streetlights - all streetlights, traffic signals, traffic signs, and traffic cameras.
- Fleet vehicles - all vehicles owned and operated by the Town of Cary. Cary’s public transportation, C-Tran, is also listed as a subset of the fleet vehicles because the Town exerts operational control even though a private organization actually operates the vehicles (see Appendix B for a detailed explanation of this and all accounting decisions).
- Water - water treatment and delivery stations.
- Wastewater - wastewater treatment and delivery stations.

Table 9 and Figure 11 show an overview of the emissions from each activity sector since 2005. For more details on the trends within each activity sector over the course of this study, please see Chapter 4.

Table 10 shows that over the entire study period, emissions from the water and wastewater sectors have represented nearly two-thirds of the Town's total emissions each year. Every sector has experienced growth in emissions, but the fleet sector is the only one that has seen its share of total emissions grow, which is a testament to how extreme has been the increase of emissions in that sector.

**Table 9**  
**Total Emissions (MTCDE)**

| By Sector    | 2005          | 2006          | 2007          | 2008          | 2009          | 2010          |
|--------------|---------------|---------------|---------------|---------------|---------------|---------------|
| Facilities   | 6,021         | 6,608         | 6,499         | 6,838         | 7,029         | 7,317         |
| Streetlights | 3,226         | 3,382         | 3,443         | 3,648         | 3,848         | 3,915         |
| Fleet        | 2,556         | 3,276         | 3,893         | 4,879         | 5,318         | 5,934         |
| Water        | 11,363        | 11,332        | 12,594        | 12,071        | 12,188        | 12,655        |
| Wastewater   | 11,188        | 13,692        | 13,549        | 13,726        | 13,862        | 14,111        |
| <b>TOTAL</b> | <b>34,353</b> | <b>38,291</b> | <b>39,978</b> | <b>41,161</b> | <b>42,244</b> | <b>43,932</b> |

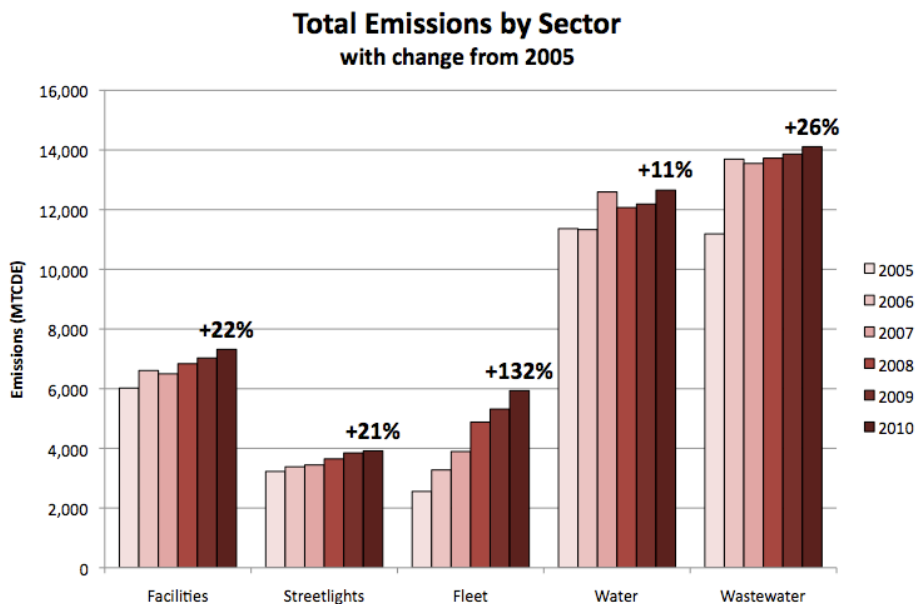

Figure 11: Total GHG Emissions by Sector, 2005-2010

**Table 10**  
**Emissions Share (% of Total)**

| By Sector    | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|--------------|------|------|------|------|------|------|
| Facilities   | 18%  | 17%  | 16%  | 17%  | 17%  | 17%  |
| Streetlights | 9%   | 9%   | 9%   | 9%   | 9%   | 9%   |
| Fleet        | 7%   | 9%   | 10%  | 12%  | 13%  | 14%  |
| Water        | 33%  | 30%  | 32%  | 29%  | 29%  | 29%  |
| Wastewater   | 33%  | 36%  | 34%  | 33%  | 33%  | 32%  |

Table 11 has combined all the various energy inputs (kWhs of electricity, therms of natural gas, and gallons of propane, gasoline and biodiesel) into the conventional MMBtu units for each activity sector. Figures 12 and 13 display side-by-side comparisons of the energy profile and emissions profile by activity sector. Because electricity is a more carbon intensive energy source, there is not a perfectly congruent relationship between the energy share and the emissions share, as Table 12 shows.

**Table 11**  
**On-site Energy Use**

| By Sector    | Unit  | 2005   | 2006    | 2007    | 2008    | 2009    | 2010    |
|--------------|-------|--------|---------|---------|---------|---------|---------|

## Source Energy and GHG Emissions

Electricity is unlike the other energy forms used by the Town in municipal operations. Natural gas, propane, gasoline, and diesel fuel are raw fuels that are combusted on-site for energy use. Electricity is a converted energy form—one that is produced off-site and purchased from a utility company. When the Town burns a raw fuel, the Town absorbs the inefficiencies of the energy transfer. Inefficiency is always present during energy transfer, but some methods convert stored energy into mechanical and/or thermal energy more efficiently than others. The EPA estimates only 12.6% of the energy potential of a gallon of transportation fuel is transferred to the drivetrain (EPA, 2011). Natural gas efficiency rates depend on many factors but current units on the market range in annual fuel utilization efficiency from near 80% up to 96% (ACEEE, 2011). In 2007 coal-fired power plants were measured to have 32% efficiency on average (NETL, 2008). These inefficiencies are not particularly noticeable by users because they have already developed performance expectations: a 20 mile-per-gallon car is expected to travel 20 miles per gallon, even though it could travel twice as far if an engine were twice as efficient.

This efficiency relationship becomes especially pertinent to building performance measurements because electricity, as a converted fuel, is delivered after some other entity has absorbed the inefficiencies involved in generation, transmission, and delivery of electricity. Oftentimes, buildings are rated on a thousand-Btu per square foot (kBtu/sf) basis where kBtu is the measurement of energy *delivered* to the building. Measuring total energy only as delivered or “on-site” energy use is such a common measurement that up to this point this document has presented energy use as the on-site usage (the sum of raw fuel and converted energy). However, raw fuel and converted energy are not directly comparable. In order to more accurately compare the actual amount of raw energy used in operations, the national average source-site ratio for each energy source is presented in Table 13 (EPA, 2011). It can be seen that both the relative carbon intensity and the site-source ratio of electricity are notably higher than the other fuels. Table 14 on the next page applies these site-source ratios across each activity sector and measures the total energy consumed, both on-site and off-site, from raw energy sources.

**Table 13**  
**Carbon Intensity and Site-Source Ratios of Energy Sources**

| Source        | kg anthropogenic CO <sub>2</sub> e/MMBtu | Site-Source Ratios (2007) |
|---------------|--|---------------------------|
| Electricity   | 149.5                                    | 3.334                     |
| Natural Gas   | 53.2                                     | 1.047                     |
| Propane       | 62.0                                     | 1.01                      |
| B20 Biodiesel | 60.0                                     | 1.01                      |
| Gasoline      | 70.2                                     | 1.01                      |

**Table 14****Source Energy Use (MMBtu)**

| By Sector    | 2005           | 2006           | 2007           | 2008           | 2009           | 2010           |
|--------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Facilities   | 130,563        | 142,994        | 142,711        | 150,044        | 154,176        | 160,350        |
| Streetlights | 70,998         | 74,443         | 76,919         | 81,484         | 85,944         | 87,441         |
| Fleet        | 39,543         | 51,106         | 60,783         | 74,956         | 81,992         | 91,644         |
| Water        | 250,093        | 249,413        | 281,309        | 269,632        | 272,242        | 282,672        |
| Wastewater   | 237,770        | 288,436        | 288,724        | 292,486        | 295,425        | 300,839        |
| <b>TOTAL</b> | <b>728,967</b> | <b>806,391</b> | <b>850,446</b> | <b>868,603</b> | <b>889,779</b> | <b>922,946</b> |

The connection of greenhouse gas emissions to energy is further exemplified by the results of Table 15. As mentioned earlier in this document, greenhouse gas inventories are essentially means by which to measure the fossil fuel content of an energy stream. Comparing emissions and “on-site” or delivered energy as in Table 12 shows that although there is a relationship between the two, measured on-site energy uses do not take into account the substantial energy losses during electricity generation and transmission. Table 15 demonstrates that the GHG emissions count corresponds far more accurately with the source energy use since it does take into account the energy used to generate converted energy forms.

**Table 15****Emissions and Source Energy Use Share in 2010**

| By Sector    | Emissions | Source Energy Use |
|--------------|-----------|-------------------|
| Facilities   | 17%       | 17%               |
| Streetlights | 9%        | 9%                |
| Fleet        | 14%       | 10%               |
| Water        | 29%       | 31%               |
| Wastewater   | 32%       | 33%               |

***Trends in Cost, Use, and GHG Emissions***

The greatest value in performing a multi-year energy and emissions inventory is that trends can be identified and used to improve efficiency. Table 16 shows the year-to-year percentage change in emissions within each activity sector with the most recent trends, the change from 2009 to 2010, highlighted by the box.

**Table 16****Year-to-Year Change in Emissions (%)**

| By Sector    | 2005 | 2006         | 2007        | 2008        | 2009        | 2010        |
|--------------|------|--------------|-------------|-------------|-------------|-------------|
| Facilities   | -    | 9.8%         | -1.7%       | 5.2%        | 2.8%        | 4.1%        |
| Streetlights | -    | 4.9%         | 1.8%        | 5.9%        | 5.5%        | 1.7%        |
| Fleet        | -    | 28.2%        | 18.8%       | 25.3%       | 9.0%        | 11.6%       |
| Water        | -    | -0.3%        | 11.1%       | -4.2%       | 1.0%        | 3.8%        |

| <b>TOTAL</b> | -    | <b>11.5%</b> | <b>4.4%</b> | <b>3.0%</b> | <b>2.6%</b> | <b>4.0%</b> |

**Table 17**  
**Change in Cost, Energy, Emissions from 2005 (%)**

|                  | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|------------------|------|------|------|------|------|------|
| Cost             | -    | 22%  | 32%  | 48%  | 53%  | 53%  |
| Energy Use       | -    | 21%  | 28%  | 34%  | 39%  | 46%  |
| Carbon Emissions | -    | 11%  | 16%  | 20%  | 23%  | 28%  |

**Changes in Energy Cost, Use, Emissions**

Figure 14: Changes in Cost, Energy Use, and Emissions

Energy costs, energy use, and emissions have all been measured and compared to their 2005 levels in Table 17 and Figure 14. The graph demonstrates that energy costs have outpaced energy use, which means that per unit energy prices have increased over this time frame. The energy price spikes of 2008 are evidenced by the rapid upward trend of the energy cost curve, followed by a leveling out as energy prices dropped over 2009 and 2010. Town energy use still increased during this time (Table 18), resulting in a level energy cost curve instead of a downward trend that would have been seen had energy consumption stabilized. Total emissions, though increasing by 28% since 2005, have increased at a slower pace than energy consumption. This is because less carbon-intensive energy sources, namely the biosolids dryer natural gas use and fleet vehicle use, have grown faster than the more carbon-intensive electricity use. If natural gas and transportation fuel represent larger shares of the Town's energy mix, emissions will continue to track lower than energy use. To maximize cost savings, it is desirable to see all three of these curves trend downward.

**Table 18**  
**Change in Cost, Energy, Emissions from 2009 (%)**

|                  | 2010 |
|------------------|------|
| Cost             | 0.1% |
| Energy Use       | 5.6% |
| Carbon Emissions | 4.0% |

Energy costs have been for the most part falling slightly from highs in 2008. As the recession ends, demand and subsequent prices are expected to increase again. These costs are displayed as dollar per MMBtu of delivered energy and do not take into account the source energy lost in generation, transmission, and delivery. It is interesting to point out that electricity is 3.5 times more expensive than natural gas, which is very similar to and explained by its site-source ratio of 3.34. Propane has tremendous costs associated with it, as it is handled and delivered in small quantities by a local vendor.

**Table 19**  
**Energy Costs per MMBtu (\$/MMBtu)**

| Source      | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|-------------|------|------|------|------|------|------|
| Electricity | \$23 | \$24 | \$25 | \$26 | \$29 | \$28 |
| Natural Gas | \$10 | \$12 | \$11 | \$13 | \$9  | \$8  |
| Propane     | \$34 | \$31 | \$30 | \$36 | \$33 | \$34 |
| Fleet Fuel  | \$16 | \$18 | \$17 | \$20 | \$16 | \$14 |

**Table 20**  
**Other Emissions Metrics**

| Metric                 | 2005      | 2006     | 2007      | 2008      | 2009     | 2010      |
|------------------------|-----------|----------|-----------|-----------|----------|-----------|
| Population             | 113,251   | 119,745  | 127,640   | 134,208   | 139,110  | 143,049   |
| Emissions per capita   | 0.303     | 0.320    | 0.313     | 0.307     | 0.304    | 0.307     |
| Employee Count (FTEs)  | 1,037.125 | 1,063.25 | 1,095.125 | 1,129.375 | 1,157.75 | 1,153.875 |
| Emissions per employee | 33.12     | 36.01    | 36.51     | 36.45     | 36.49    | 38.07     |

Table 20 presents emissions, population, and the employee count of the Town as well as the mixed metrics of emissions per capita and emissions per employee. When looking at Figure 15 that plots the changes in values from 2005, emissions growth and population growth have mostly mirrored one another while both outpaced the growth in town employees. (The flattening of the employee curve from 2009 and 2010 reflects the hiring freezes that most municipalities put in place during the recession.) Combining the

**Growth: Emissions, Population, Employee Count**

Figure 15: Growth, 2006-2010

population and employee growth trends with emissions growth to create mixed metrics can distort the overall trends by measuring two mostly independent metrics, as demonstrated in Figure 16. If emissions per capita decrease, as they have since 2006, this could be due to decreasing emissions or from an increasing population. In Cary's case, the growth in population since 2006 has outpaced the growth in emissions. This means the emissions per capita has fallen, but total emissions have still increased. If carbon emissions were taxed, the tax expenditure by the Town still would increase. The emissions per employee metric had been very stable from 2006 to 2009 but then suddenly trended upward sharply in 2010. Just by looking at the metric, it is difficult to tell whether this increase is due to cutting employees or from an increase in emissions. In this case, both contributed. The point is that mixed metrics can be an informative item, but policy should never be attached to a mixed emissions metric because there could easily be unintended means used to accomplish a stated result.

### Various Emissions Metrics

Figure 16: Various Emissions Metrics, 2006-2010

## GHG Emissions Forecast

In this report, GHG emissions are forecasted to the year 2020 by applying an average annual growth rate of 3.5%. As Table 6 showed, emissions grew by 11.5% from 2005 to 2006 mostly from the addition of the biosolids dryer. Growth slowed to an average of 3.5% annually between 2006 and 2010. Assuming that the same trends experienced during this 5-year period remain in place for the next 10 years, total emissions of municipal operations from the Town of Cary will reach nearly 62,000 MTCDE by 2020, as demonstrated by Figure 17. (For the purposes of the graph, the baseline was arbitrarily selected as 2009 only to serve as a point of reference.)

Figure 17: GHG Emissions Forecast, 2005-2030

## 4. GHG EMISSIONS IN DETAIL

This chapter provides additional tables and explanations of energy and emissions activities within each activity sector and among departments of the Town. The department section is merely an introduction to departmental reports compiled as dashboard style report cards in Appendix D.

### *Activity Sectors in Detail*

**FACILITIES:** The majority of emissions from the facilities sector are from electricity use in buildings—a stock that measured roughly 480,000 square feet in 2010. Electricity use represented 86% of emissions in facilities, natural gas 12%, and propane 2%. Among electricity use in facilities in 2010, 74% of emissions came from buildings, 17% from sport lighting, and 5% from other outdoor lighting. Given the significant share of emissions from buildings, Table 21 lists the ten most energy-intensive buildings by kBtu per square foot of delivered energy, and Table 22 lists the top ten buildings by overall GHG emissions.

**Table 21**  
**Most Energy Intensive Buildings in 2010**

| Building                                     | Square Feet | Site Energy<br>KBtu/sqft | Source Energy<br>KBtu/sqft |
|--|-------------|--------------------------|----------------------------|
| Town Hall B                                  | 55,226      | 208.3                    | 488.9                      |
| Town Hall C                                  | 52,951      | 169.0                    | 430.8                      |
| North Cary Water Reclamation Office Building | 9,200       | 168.7                    | 563.3                      |

| Fleet Building                              | 13,240      | 165   | 12.4         |
| Middle Creek Park Ball Tower                | 5,612       | 123   | 21.9         |

**STREETLIGHTS:** The streetlights activity sector includes streetlights, traffic signals, traffic signs, and traffic cameras that only use electricity as their energy source. Energy use in streetlights accounts for 99.1% of the sector’s emissions totals, so Table 23 includes a historic bulb count and kWh estimate. The bulb count roughly parallels the kWh totals. Utilities do not meter streetlight activity and instead include a kWh energy use estimate for each bulb type in the terms of the light contract. Because bulbs have a number of different wattages, the growth in total kWhs only roughly parallels growth in the bulb count.

**Table 23**  
**Streetlight Count**

|                     | 2005      | 2006      | 2007      | 2008      | 2009      | 2010      |
|---------------------|-----------|-----------|-----------|-----------|-----------|-----------|

| Total kWh in Sector | 6,229,747 | 6,532,029 | 6,749,332 | 7,149,868 | 7,541,195 | 7,672,603 |
| Annual % Change     | -         | 4.9%      | 3.3%      | 5.9%      | 5.5%      | 1.7%      |

**FLEET:** Over the six-year study period, the vehicle fleet has more than doubled in size from 333 vehicles and large, non-road equipment pieces (2005) to 681 vehicles and large equipment pieces (2010). Some of this growth results from the reabsorption of several activities that were previously contracted out, such as waste hauling. However, other programs such as recycling collection simply have expanded<sup>1</sup>. Nonetheless, the degree of growth seen in this activity sector is either just extremely high or an error due to inadequate historical data. The fleet division was queried on this issue but offered no feedback, so the data received have been accepted as accurate for the purposes of this report. Table 24 includes details of the fleet energy use and total emissions.

**Table 24**  
**Fleet Sector Emissions Statistics**

|                         | 2005      | 2006      | 2007        | 2008        | 2009        | 2010        |

| Gasoline Use (gals)     | 149,861   | 174,876   | 207,106     | 277,780     | 284,148     | 326,965     |
| Total FY Cost (\$)      | \$631,710 | \$919,346 | \$1,048,516 | \$1,510,306 | \$1,323,534 | \$1,254,149 |
| Vehicle Count (#)       | 333       | 397       | 471         | 554         | 609         | 681         |
| Biogenic CO2 (tonnes)   | 284       | 399       | 476         | 549         | 634         | 693         |

Unfortunately, the fleet data also had severe errors from the input of erroneous odometer readings. This recorded annual utilization to range from negative 250,000 miles in one year to up to 500,000 miles, both of which are unmistakably errors. This forced the removal of almost 10% of all fleet mileage data and severely hindered accurate tracking of miles per gallon (MPG) and total vehicle miles, two very useful indicators within a fleet. Not only does incorrect data affect a fleet analysis, but the institutional acceptance of these practices can easily lead to unaccounted and untraceable fuel disbursements.

<sup>1</sup> The Town of Morrisville contracts the Town of Cary to manage their fleet vehicles, and those vehicles have been properly discarded from the Town of Cary’s fleet data.

Also note that vehicle counts included all vehicles that had activity records within a given calendar. If a vehicle was purchased as a replacement for another vehicle, both vehicles were counted unless the replacement occurred exactly on December 31 or January 1.

Since mileage data are unavailable, the next best metric to use is vehicle counts by vehicle type. As demonstrated by Figure 18, the most common vehicle type in the fleet is the light-duty gasoline truck. Heavy-duty diesel trucks, though accounting for only 17% of the composition of the fleet, represent 33% of the total emissions. Increasing the fuel efficiency of heavy-duty equipment represents a significant reduction opportunity in most municipal fleets. Oftentimes among heavy-duty equipment, a 10% fuel efficiency gain might mean only a 0.3 MPG improvement that can be accomplishable through anti-idling campaigns, strict maintenance practices, or after-market retrofit kits.

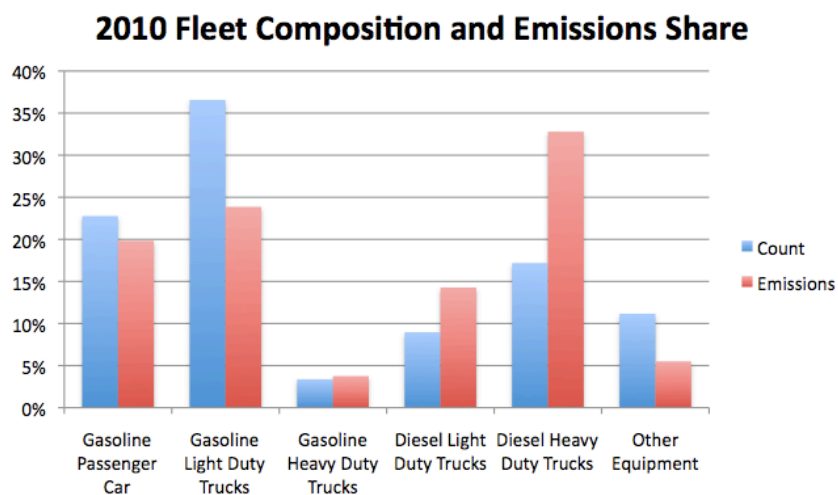

Figure 18: Fleet Composition and Emissions Share, 2010

Activity from Cary's transit provider, C-Tran, is included in the fleet totals and presented as a subset of data in Table 25. Mileage information from the transit vehicles was of poor quality and was therefore completely disregarded, so only fuel use records were used for this analysis. With the introduction of many new gasoline vehicles, an item of interest in future inventories could be to track the performance and GHG emissions of the new vehicles compared to the existing vehicles.

**Table 25**  
**Transit Emissions Statistics**

|                           | 2005   | 2006   | 2007   | 2008   | 2009   | 2010   |
|---------------------------|--------|--------|--------|--------|--------|--------|
| Transit Emissions (MTCDE) | 349    | 599    | 630    | 659    | 801    | 923    |
| B20 Use (gals)            | 28,721 | 60,410 | 61,126 | 60,987 | 73,768 | 65,933 |
| Gasoline Use (gals)       | 12,941 | 11,863 | 14,750 | 18,151 | 22,386 | 43,511 |
| Vehicle Count (#)         | 20     | 29     | 27     | 28     | 36     | 59     |
| Biogenic CO2 (tonnes)     | 54     | 114    | 116    | 115    | 139    | 125    |

**WATER:** Emissions from water treatment and delivery, as expected, mirror the trends of the volume of water treated. Increases in emissions in 2007 correspond with increases in the volume of water delivered, and decreases in emissions followed less usage during the 2008 drought. All energy used in the water sector is from electricity use (with the exception of one very small natural gas account). The Cary/Apex Water Treatment Plant accounted for 58% of the water sector’s energy use and emissions in 2010. The water intake plant accounted for 23%, and energy use at other pump stations across town made up the other 19%. Even though the cost of the plant is shared with Apex, the Town of Cary operates the plant and therefore is responsible for reporting its emissions. Table 26 shows specific water sector data including the proposed performance indicator of MTCDE per million gallons (MG) of treated water.

**Table 26**  
**Water Sector Emissions**

|                                | 2005   | 2006   | 2007   | 2008   | 2009   | 2010   |
|--------------------------------|--------|--------|--------|--------|--------|--------|
| Volume of Water Treated (MG)   | 5,695  | 5,672  | 6,712  | 6,066  | 5,871  | 6,247  |
| Annual % Change                |        | 0%     | 18%    | -10%   | -3%    | 6%     |
| Water Sector Emissions (MTCDE) | 11,363 | 11,332 | 12,594 | 12,071 | 12,188 | 12,655 |
| MTCDE/MG                       | 2.00   | 2.00   | 1.88   | 1.99   | 2.08   | 2.03   |

**WASTEWATER:** The wastewater sector primarily consists of two wastewater treatment plants—the North Cary Wastewater Reclamation Plant (NCWRF) and the South Cary Wastewater Reclamation Facility (SCWRF). Less than 1% of energy use in the sector is for wastewater lift stations. Electricity is the primary energy source within the sector with the notable exception of the biosolids dryer at the SCWRF that operates on natural gas. The NCWRF uses 48% of the electricity from the sector and 40% of the overall energy. The SCWRF uses 52% of the electricity and 59% of the overall energy. Table 27 lists performance metrics in the sector including two proposed performance indicators: the MTCDE per million gallons (MG) of treated wastewater and the MTCDE from the biosolids dryer per dry ton of biosolids created.

**Table 27**  
**Wastewater Sector Emissions**

|  | 2005   | 2006   | 2007   | 2008   | 2009   | 2010   |
|--|--------|--------|--------|--------|--------|--------|
| Wastewater Emissions (MTCDE)           | 11,188 | 13,692 | 13,549 | 13,726 | 13,862 | 14,111 |
| Volume of Wastewater Treated (MG)      | 4,196  | 4,309  | 4,124  | 3,988  | 4,071  | 3,940  |
| MTCDE/MG                               | 2.67   | 3.18   | 3.29   | 3.44   | 3.40   | 3.58   |
| Emissions from Biosolids Dryer (MTCDE) | 258    | 1,943  | 2,001  | 1,895  | 1,826  | 2,025  |
| Biosolids produced (dry tons)          | 0      | 3,053  | 3,044  | 2,910  | 2,866  | 3,108  |
| MTCDE/dry ton                          |        | 0.64   | 0.66   | 0.65   | 0.64   | 0.65   |

## Departments in Detail

Activity sector information is helpful, but municipal budgets are crafted around departments rather than sectors. This report includes a complete department-by-department view of energy and emissions in Appendix D. This section serves as an introduction for those reports. Appendix D includes energy report cards for all Town departments as distinguished by the Town budget.

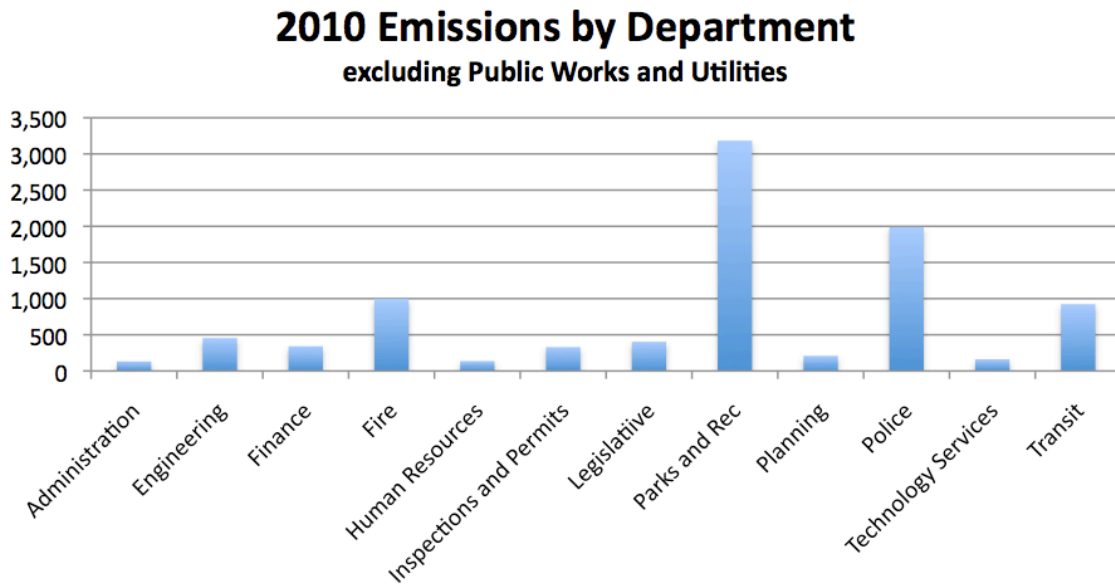

Figure 19: Emissions by Department, 2010

Although the Public Works and Utilities Department is technically a single unit, this report split them based on funding sources. The Public Works department listed in the departmental reports is funded by the general fund while the Utilities Department utilizes the utilities fund revenue stream. Considering over 60% of the Town's emissions result from water and wastewater processes, it is no surprise that the Utilities Department has the largest energy use. Public Works is the next largest energy user since the streetlights and much of the fleet usage falls into that department. Figure 19 omits these two departments due to scale concerns and still shows there are a limited number of departments with significant emissions. These are the departments that have their own facilities. The rest share office space at Town Hall or James Jackson, and some may operate a small number of fleet vehicles. Because there currently are no submeters at town facilities, Town Hall and James Jackson utilities were split using the financial splits used by the Finance department. Exact splits are identified in the departmental reports. Also see Appendix C for a collection of additional tables with departmental data.

## 5. COMPARISONS WITH OTHER MUNICIPALITIES

Comparing GHG emissions among municipalities is a delicate exercise that deserves a word of warning. Because municipalities are unique in the services offered to residents, it is very difficult to compare municipalities to one another in terms of GHG emissions. Some municipalities have significant transit operations compared to Cary’s small operation. Some municipalities rely on counties or other entities for water or wastewater treatment, thus escaping having to report those emissions. As demonstrated earlier when describing the mixing of emissions metrics with some other indicator, a lower result does not clearly imply a “better” emissions performance. Nonetheless, it can be helpful to see how Cary stacks up to other North Carolina municipalities that have completed a GHG inventory.

**Table 28**  
**GHG Comparisons with Other North Carolina Municipalities**  
 (From most recent year reported, as denoted in parentheses)

| Municipality         | Municipal Operations Emissions (MTCDE) | Population (Reporting year) | Emissions per capita (MTCDE/person) | Employees (# of FTE) | Emissions per employee (MTCDE/employee) |
|----------------------|--|-----------------------------|-------------------------------------|----------------------|---|
| Cary (2010)          | 43,932                                 | 143,049                     | 0.307                               | 1,154                | 38.1                                    |
| Asheville (2010)     | 33,053                                 | 83,393                      | 0.396                               | 1,149                | 28.8                                    |
| Chapel Hill (2010)   | 15,733                                 | 57,233                      | 0.275                               | 702                  | 22.4                                    |
| Durham (2005)        | 158,710                                | 241,700                     | 0.657                               | N/A                  | N/A                                     |
| Raleigh (2007)       | 151,494                                | 392,600                     | 0.386                               | 3,000                | 50.5                                    |
| Winston-Salem (2006) | 141,500                                | 217,342                     | 0.651                               | 2,500                | 56.6                                    |

As the results in Table 28 are considered, keep in mind the following facts that influence the GHG emissions results presented:

- Asheville operates a large transit agency and three water treatment plants, but Buncombe County provides wastewater treatment (Asheville, 2010).
- Chapel Hill operates one of the largest transit agencies in the state but does not handle any water or wastewater treatment functions.
- Durham City-County municipal operations include an extensive transit agency, water and wastewater treatment, landfill activities, and even the school system (Durham, 2007).
- Raleigh operates a large transit agency, water and wastewater treatment, landfill activities, and a large number of civic buildings (Raleigh, 2008).
- Winston-Salem operates a transit agency, water and wastewater treatment, and landfill activities (Winston-Salem, 2007)

Emissions per capita results show that Cary rivals Chapel Hill for the lowest in the group, but again, the two towns have very different activity profiles. As for emissions per employee, this is a metric that gives especially misleading information. To have a high emissions per employee count could mean that either absolute emissions are high, the Town is understaffed due to budget cuts or high efficiency at staffing, or both.

## 6. NITROGEN OXIDES (NO<sub>x</sub>) EMISSIONS INVENTORY

In addition to an energy and GHG inventory, the Town has requested an emissions inventory of nitrogen oxides (NO<sub>x</sub>), a criteria air pollutant. NO<sub>x</sub> are a group of highly reactive pollutants that include nitrogen dioxide (NO<sub>2</sub>), nitric oxide (NO), nitrous acid (HNO<sub>2</sub>), and nitric acid (HNO<sub>3</sub>). According to the EPA, this class of gases causes acute respiratory problems even with short-term exposure (EPA, 2009). The EPA also reports that NO<sub>x</sub> can react with ammonia, moisture, or other compounds to form small particles that can penetrate deeply into the lungs, causing severe respiratory and heart disease.

Sources of NO<sub>x</sub> emissions include on-road vehicles, non-road equipment, electricity generation, fossil fuel combustion, waste disposal, and industrial processes. In North Carolina in 2005, the EPA estimates 460,415 tons of NO<sub>x</sub> were emitted with 43% from on-road vehicles, 25% from electricity generation, 17% from non-road equipment, 9% from other fossil fuel combustion, and 3% each from waste disposal and industrial processes. Unlike greenhouse gases, NO<sub>x</sub> emissions are very difficult to measure accurately because NO<sub>x</sub> rates can fluctuate with driving speed, vehicle load, ambient temperatures, and other conditions. Even the emissions factors provided by the EPA are estimates of NO<sub>x</sub> emissions.

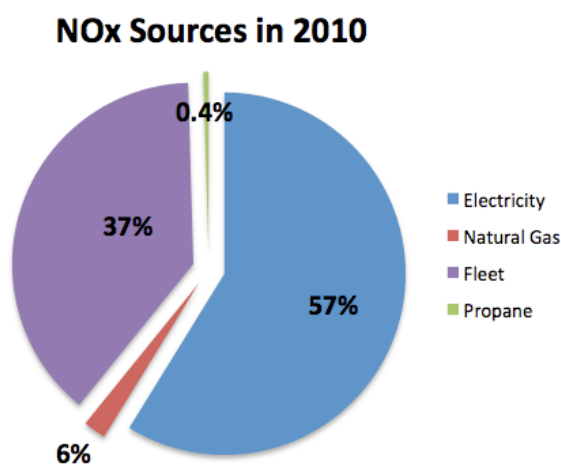

Figure 20: NO<sub>x</sub> Sources in Cary, 2010

Those NO<sub>x</sub> sources pertinent to Cary's municipal operations include fleet vehicles, non-road equipment within the town fleet, combustion of natural gas and propane at facilities, and indirectly electricity generation. Waste disposal is typically a very low source, and indirect NO<sub>x</sub> emissions from waste disposal have not been included because Cary does not operate a landfill. The EPA publishes emissions factors for NO<sub>x</sub> from electricity generation (through eGRID), propane combustion, and natural gas combustion. The manufacturer of the biosolids dryer at the South Cary Water Reclamation Plant supplied a NO<sub>x</sub> factor of 0.036 lbs/MMBtu for that equipment. The biosolids dryer utilizes a gas recirculation to

**Table 29**

### NO<sub>x</sub> Emissions by Source (kg)

| By Source         | 2005          | 2006          | 2007          | 2008          | 2009          | 2010          |
|-------------------|---------------|---------------|---------------|---------------|---------------|---------------|
| Electricity       | 42,787        | 44,731        | 36,672        | 36,868        | 37,587        | 38,486        |
| Natural Gas       | 649           | 1,222         | 1,124         | 1,193         | 1,215         | 1,328         |
| Fleet             | 13,204        | 14,777        | 17,612        | 20,482        | 22,829        | 25,319        |
| Propane           | 133           | 272           | 302           | 269           | 273           | 306           |
| <b>TOTAL (kg)</b> | <b>56,774</b> | <b>61,001</b> | <b>55,710</b> | <b>58,811</b> | <b>61,904</b> | <b>65,439</b> |
| Annual Change     |               | 7.4%          | -8.7%         | 5.6%          | 5.3%          | 5.7%          |

reduce NOx emissions. Fleet vehicle emission rates were used from an ICLEI emissions tabulation software program called Clean Air Climate Protection (CACP), which provided NOx rates by vehicle type and model year. Non-road equipment was then estimated from the on-road tally using the state ratio of on-road to non-road emissions from 2005.

Figures 20 and 21 demonstrate the NOx sources and trend within Cary. The updated eGRID emission rate for the years 2007 to 2010 was 25% lower than the factor from 2005 and 2006, thus resulting in a decrease from 2006 to 2007.

Figure 21: Total NOx Emissions, 2005-2010

## 7. CONCLUSIONS

### *Reaction to Results*

Energy use has been steadily increasing from every energy source, within every activity sector, and in every department in the Town of Cary's municipal operations. This consistent upward trend in energy consumption, combined with the indication from utility companies that higher energy costs are forthcoming, are all but guarantees that overall energy costs for the Town will continue to rise if efficiencies are not realized. Duke Energy (which is planning to merge with Progress Energy later this year) recently disclosed intentions to raise electricity prices by 6.6% in September 2011. Using this estimate that electricity prices could rise by 6.6%, the Town could see a yearly increase of over \$400,000 per year in electricity costs. This amount could be even higher if consumption rates do not stabilize. Creating and implementing a Strategic Energy Plan that identifies and prioritizes savings opportunities may mitigate these expected future cost increases. It is simply too costly for the Town to allow energy use to continue to be an unmanaged expense.

Of particular note, over 60% of the Town's GHG emissions result from the water and wastewater treatment processes. It is understood that this provides a basic need to the entire community, but it also highlights the fact that water is more than just a resource. Conserving water also means conserving energy, so it is quite accurate to view water as a form of energy. Cary already has staff dedicated to promoting and achieving water conservation. This report will hopefully bring more attention to those efforts. If community-wide demand can be lowered, there will be both less water *and* less wastewater requiring energy-intensive treatment.

### *Concerns Identified*

In addition to the concern that vehicle data are outright missing from earlier years, the fleet division provided vehicle mileage data that were unreliable. Some vehicles reported up to 500,000 miles of usage in one year, while others reported negative 250,000 miles. The C-Tran mileage numbers were especially unusable for this report. This greatly hindered a more thorough analysis of the fleet. Departmental average fuel economy contained data that was estimated based on EPA fuel economy estimates and/or limited data from other years.

One known source of emissions that was not included in this report was diesel fuel used to operate the backup electricity generator systems at vital town buildings. No data were available for these sources. It is expected that these emissions would be less than 1% of the municipal total; not including them in this report was not a significant departure for the purposes of this report. It is recommended that Town staff include the gallons of diesel burned per hour in all Town-owned generators to assist in emergency preparedness documents and plans. In the event of a crisis that cuts electricity and limits diesel supply, this could aid in the prioritization and distribution of fuel.

## ***Suggested Actions***

With a detailed energy and emissions inventory now complete, the Town of Cary is empowered to make confident energy decisions emboldened by reliable data. Suggestions for actionable items include:

1. ***Begin an energy management program:*** With \$8.3 million in annual energy expenses, even a 5% decrease in energy costs translates into a substantial savings. A well-run energy management program should save the Town far more than it costs to implement and would provide professional oversight of what currently is an \$8.3 million annual expenditure.
  - a. *Add submeters/smart meters to large facilities:* The South and North Cary Water Reclamation Plants, the James Jackson complex, the Town Hall complex, and several of the large recreational complexes with sport lighting could benefit from adding smart meters behind the existing meters. As part of a broader energy management plan, smart metering allows energy use in high-use facilities to be managed in real-time to optimize cost savings.
  - b. *Utilize software options:* There are many software options available to assist energy and building managers in tracking energy usage. EPA's Energy Star Portfolio Manager is a free database software that includes a weather correcting option. Many private "software as a service" companies offer versions that perform database and reporting actions. Due to the size of the Town, a software system is a logical option to begin storing energy information in a reliable and easily transferable manner.
  - c. *Investigate reduction opportunities:* LED streetlights, building efficiency improvements, and more efficient fleet vehicles represent "low hanging fruit" that can possibly result in significant emissions and cost savings.
2. ***Create a strategic energy plan:*** Work with the North Carolina State Energy Office and representatives from relevant departments to draft a strategic energy plan that establishes the steps necessary for the Town to save energy costs and move toward energy stability. This inventory and its accompanying Excel data file should be used as a roadmap to determine energy saving opportunities on a department-by-department and even account-by-account basis.
3. ***Implement a fleet efficiency policy to guide new vehicle purchases:*** Not only does constant turnover in the vehicle fleet make opportunities available for more energy efficient replacements, but also a vehicle-by-vehicle examination of the fleet has shown that many vehicles are oversized for their uses. By implementing an effective policy that promotes the use of vehicles with high fuel economy, alternative fuels, electric vehicles, and hybrid vehicles, fleet emissions should stabilize and soon begin decreasing.
4. ***Promote energy literacy throughout the Town:*** Promoting energy literacy means instructing staff on how municipal energy is consumed, billed, and saved and including energy use updates in senior management meetings and general departmental staff meetings. After appointing an energy manager, enlist that person to act as an energy liaison to the Town's departments.

## Appendix A: Fossil Fuels, Climate Science, and GHG Reduction Targets

### Fossil Fuel Use

Especially since the Industrial Revolution, human activity has been consuming ever-increasing quantities of fossil fuels. According to the U.S. Energy Information Administration (EIA), fossil fuels, which include coal, natural gas, and petroleum, were the source of over 86% of the world's energy consumption in 2006<sup>1</sup>. These fuels provide the majority of our energy used to produce electricity, operate our motor vehicles, and heat our buildings. Fossil fuels are the dominant energy source because they are found in large quantities throughout the world, contain a substantial amount of energy, and are relatively easy to extract. This abundant supply of cheap energy has fueled centuries of exceptional economic growth throughout the world and in the United States.

However, we are beginning to realize that there are environmental costs to our energy choices. Fossil fuels are potent energy sources because they possess energy in the form of chemical bonds. In order to release that energy, combustion must take place—the fuel must be burned. That reaction releases energy and a byproduct: gaseous carbon dioxide. Because fossil fuels have essentially been storing energy and carbon for millions of years below the earth's surface, the carbon within fossil fuels has been withheld from the

Figure 22: The Carbon Cycle. (Image from NASA Earth Science Enterprise.)  
[http://earthobservatory.nasa.gov/Features/CarbonCycle/carbon\\_cycle4.php](http://earthobservatory.nasa.gov/Features/CarbonCycle/carbon_cycle4.php)

naturally occurring carbon cycle (Figure 22). The earth's ecosystem had reached a carbon equilibrium that helped shape and support our current climate and biodiversity. But as human activity continues to transfer carbon dioxide from fossil fuels to the atmosphere, the natural cycle becomes disrupted and excess atmospheric carbon dioxide builds. These rising concentrations of carbon dioxide threaten our climate.

<sup>1</sup> Energy Information Administration (2006), *International Energy Annual 2006*

## Greenhouse Gases and Climate Change

Carbon dioxide, water vapor, nitrous oxide, methane, and ozone are naturally occurring greenhouse gases. Radiation from the sun heats the earth, and these natural greenhouse gases trap some of that heat, like a blanket, through the greenhouse effect. The greenhouse effect is important in regulating the earth's temperature; without it, the earth would experience a colder climate and likely larger temperature differences during 24-hour periods. However, as concentrations of greenhouse gases increase from human activities such as combustion of fossil fuels, the greenhouse effect becomes stronger and causes the average global temperature to rise (the blanket becomes thicker). The atmospheric carbon dioxide concentration is considered the leading indicator for measuring the greenhouse effect. (Although water vapor is the most prevalent greenhouse gas, it does not force the greenhouse effect but rather acts as a positive feedback because atmospheric water vapor concentrations are dependent upon temperature.) The

Figure 23: CO<sub>2</sub> concentrations and temperature. (Image from the EPA.) [http://www.epa.gov/climatechange/science/pastcc\\_fig1.html](http://www.epa.gov/climatechange/science/pastcc_fig1.html)

Vostok ice cores from Antarctica have shown a correlation between carbon dioxide and global temperature, as seen in Figure 23. Throughout the past 600,000+ years, the atmospheric carbon dioxide concentration has fluctuated (but never exceeded 300 ppm) and carbon dioxide corresponded with temperature fluctuations. Additional ice cores from the Law Dome in Antarctica show that from 1006 CE until the Industrial Revolution, carbon dioxide concentrations were stable between 275 and 284 ppm.<sup>2</sup> Since 1959, the National Oceanic and Atmospheric Administration (NOAA) has recorded the atmospheric carbon dioxide concentration. That average annual concentration has risen every year since 1959 and was at an alarming 389.8 ppm in 2010. Over the past decade, NOAA data show the average carbon dioxide concentration has been rising by roughly 2 ppm per year.

Although the burning of fossil fuels is the primary source of anthropogenic greenhouse gas emissions, there are many other sources of direct emissions from human activities including cement production (which involves chemical reactions that emit carbon dioxide), solid waste accumulation (which causes methane production), and agricultural activities, such as livestock that emit methane and fertilizers that emit nitrous oxide. There are also

<sup>2</sup> D.M. Etheridge, et al. (1998). *Historical CO<sub>2</sub> records from the Law Dome DE08, DE08-2, and DSS ice cores*. Carbon Dioxide Information Analysis Center, Oak Ridge National Laboratory, U.S. Department of Energy.

trace emissions of synthetic chemicals and refrigerants such as hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs) that increase the greenhouse effect. According to the Carbon Dioxide Information Analysis Center at the Department of Energy, methane and nitrous oxide concentrations have been increasing since the Industrial Revolution but at a slower rate than carbon dioxide and are still at concentrations 200 and 1200 times lower than carbon dioxide, respectively.<sup>3</sup>

The U.S. Environmental Protection Agency (EPA) reports that scientific evidence has determined with virtual certainty that:

- Human activities are changing the composition of Earth's atmosphere.
- The atmospheric buildup of greenhouse gases is largely the result of human activities such as the burning of fossil fuels.
- An “unequivocal” warming trend of about 0.56 to 0.92°C occurred from 1906-2005.
- The major greenhouse gases emitted by human activities remain in the atmosphere for periods ranging from decades to centuries. It is therefore virtually certain that atmospheric concentrations of greenhouse gases will continue to rise over the next few decades.
- Increasing greenhouse gas concentrations tend to warm the planet.<sup>4</sup>

The existence of global warming and beginning of climate change is fully supported by climate science. The only debate within the scientific community surrounds the predictions of how much and how fast the global temperature will rise. With rising global temperatures and rising carbon dioxide concentrations, a wide range of climate impacts are expected by the Intergovernmental Panel on Climate Change (IPCC), including the following:

- Changes in average regional precipitation with some regions experiencing an increase, others a decrease
- An increase in the intensity of precipitation events that will lead to more floods
- More intense but less frequent tropical cyclones
- Sea-level rise and ocean acidification

An extreme loss of biodiversity, increased human health concerns, and significant disruptions in food chains are likely to occur if climate change continues unabated.

Although no official global targets have been set, it is widely accepted that in order to avert dangerous levels of climate change, the earth's average temperature must not rise more than 2°C above pre-industrial levels. It has already risen about 0.74°C. Dr. James Hansen, head of the Goddard Institute of Space Science at NASA and a leading climate scientist, has joined other scientists to calculate 350 ppm as the safe upper limit for carbon dioxide concentrations.<sup>5</sup> To reiterate, carbon dioxide was at 389 ppm in 2010.

## Reduction Targets and Local Commitments

In 2007, the IPCC established that in order to achieve a stabilization of atmospheric carbon dioxide equivalent of around 450 ppm (this includes carbon dioxide and the other anthropogenic greenhouse gases), developed countries would have to reduce total greenhouse gas emissions 80% to 95% below 1990 levels by 2050.<sup>6</sup> President Barack Obama and his administration had been calling for reductions throughout the U.S. of 17% below 2005 levels by 2020 and 83% by 2050.

Cary expressed a commitment to environmental sustainability by becoming a member of ICLEI-Local Governments for Sustainability in 2008. ICLEI is a membership association of local governments dedicated to climate protection and sustainable development by providing climate protection analysis tools and assistance to local governments. ICLEI has taken the lead in organizing communities to reduce greenhouse gas emissions and has established “Five Milestones” that provide a simple, standardized approach to reaching the goal of climate mitigation. The first step, achieved by this document, is to conduct a detailed greenhouse gas emissions inventory for a selected baseline year and a forecast of emissions to a target year.

Figure 24: The Five Milestones to achieving climate mitigation

Many other cities in North Carolina have conducted GHG emissions inventories and have gone another step to make pledges to reduce the greenhouse gas emissions from their municipal operations. Those commitments include the following cities and targets:

- Asheville, an 80% absolute reduction from 2007 levels by 2050
- Chapel Hill, a 60% reduction per capita from 2005 levels by 2050
- Durham, a 50% absolute reduction from 2005 by 2030
- Winston-Salem, a stabilization of emissions by 2010.

On the national scale, President Obama announced in January 2010 that the federal government would set an example for the nation and reduce the greenhouse gas emissions from federal operations 28% below 2008 levels by 2020.<sup>7</sup>

## Appendix B: Additional GHG Accounting Details

### *Establishing Organizational Boundaries*

The first accounting structure for reporting municipal operation emissions is to define the organizational boundary: what departments, services, and organizational structures are considered part of “municipal operations?” The ICLEI protocol allows for organizational boundaries to be established based on operational control or financial control. The state of California requires municipalities to report according to operational control, and ICLEI suggests using operational control to prevent some instances of double counting that can occur when using financial control boundaries. To follow the conventional approach and to prevent possible double counting of emissions when regional counts are assembled between multiple organizations, the inventory for the Town of Cary has been conducted using an operational control boundary where operational control is defined as:

- 1) *Wholly owning an operation, facility, or source; or*
- 2) *Having the full authority to introduce and implement operational and health, safety and environmental policies (including both GHG- and non-GHG-related policies).<sup>8</sup>*

Many functions clearly fall under the Town’s operational control since the Town fully owns numerous facilities and can set operational policies in other instances. Emergency services (police and fire rescue), parks and recreational facilities and services, and administrative services (finance, planning, engineering, etc.) are among those activities that are clearly under the Town’s operational control. All fleet vehicles owned and operated by the Town are within the organizational boundary, including the vehicles used by the transit organization, C-Tran. Because the Town has written a detailed contract that actually exerts operational decisions over the operators of C-Tran (bus size, fuel type, routing, etc.), the Town must associate the emissions from C-Tran within its operational boundaries.

There are at least 168 traffic signals across Cary, most of which are owned by the North Carolina Department of Transportation (NCDOT) with only 16 owned by the Town. Those signals owned by the Town are within its operational control. The NCDOT signals, although they serve Cary and are partially managed by the Town’s traffic engineers, are considered under NCDOT’s operational control. The Town pays the operational costs for, performs maintenance on, and sets all signalization patterns for town-owned signals. In contrast, NCDOT pays the operational costs for the NCDOT-owned signals and reimburses Cary for all maintenance and other services performed on those signals. In these instances, however, NCDOT ultimately has the authority to control where their signals are placed and how they are signalized. NCDOT traffic signals fall outside of the Town’s operational control.

Streetlights are another special case. In Cary and many other municipalities served by Progress Energy, the utility owns the streetlights while the municipality leases them. This arrangement is addressed in the ICLEI protocol as “Emissions from Leased Assets.” Even

---

<sup>8</sup> ICLEI (2010), *Local Government Operations Protocol*, Version 1.1, page 14

though another entity owns the equipment, the lessee (in this case, the Town) is responsible for the emissions because the lessee has operational control over the leased equipment. State-owned roads are required to be lit by the municipality according to state guidelines while streetlight placement on town-owned roads is guided by policy developed by the town. Because Cary is leasing the property yet still has operational control over the emission source, all streetlights paid for by the Town are considered under the Town's operational control despite being owned by Progress Energy.

The streetlight arrangement is very similar to joint-use and partnered spaces, such as the Middle Creek Community Center, USA Baseball Training Complex, and WakeMed Soccer Park. Although the Town entered into a construction agreement with another organization and may not own the office space itself, these emission sources are under the Town's operational control because it controls the operations and energy use. The converse is also true when the Town is the lessor, as in the case of the Koka Booth Amphitheatre at Regency Parkway. Since the Koka Booth Amphitheatre controls the facility, they are responsible for the emissions. If reporting these emissions at all, the Town could report these as indirect emissions (see *Operational Boundaries* section), since as a landlord the Town does have indirect responsibility for the efficiency of the facility.

### ***Operational Boundaries***

Once the organizational boundary has been established, operational boundaries are determined to organize the emissions into one of three standard classifications called emission scopes. The three scopes of greenhouse gas emissions are as follows:

*Scope 1: All direct greenhouse gas emissions that are emitted on site.*

*Scope 2: Indirect greenhouse gas emissions associated with the consumption of purchased or acquired energy in the form of electricity, steam, heating, or cooling.*

*Scope 3: All other indirect emissions not covered in Scope 2, such as emissions resulting from the extraction and production of purchased materials and fuels, transport-related activities in vehicles not owned or controlled by the town (e.g. employee commuting and business travel), outsourced activities, waste disposal, etc.<sup>9</sup>*

Scope 1 and 2 emissions are considered the "total emissions" of the reporting entity. Scope 1 emissions are essentially tailpipe emissions that are generated on site as a direct result of operations that are within the organizational boundary of the reporting entity. Scope 2 emissions are those that result from purchased energy but are emitted off site, typically at a facility operated by a utility provider to generate electricity, steam, or chilled water. In the case of the Town of Cary, Scope 2 emissions comprise just purchased electricity. Even though another entity (Progress Energy, Duke Energy, or those who supply the Town of Apex) is directly producing the emissions reported as Scope 2, those emissions are a direct consequence of the energy use of town operations. The town controls the thermostat, so to speak, and can regulate their electricity consumption even though they cannot necessarily control the type of materials used to generate that electricity.

---

<sup>9</sup> ICLEI Local Government Operations Protocol, Version 1.1, page 22

Scope 3 emissions are from activities that generally fall outside of the reporting entity's organizational boundary yet are still indirectly related to the entity's operational decisions. Scope 3 emissions are optional to report as they are, by nature, another entity's Scope 1 or Scope 2 emissions. Solid waste landfill disposal, contracted services, employee travel, and employee commuting are perhaps the most significant Scope 3 emissions for Cary. As an example as to why these are Scope 3, an employee commuting to work is the one responsible for the direct Scope 1 tailpipe emissions from their personal vehicle. If all businesses and individuals inventoried their greenhouse gas emissions, that employee would report their commuting emissions as part of their personal Scope 1 emissions, while their employer should account for those emissions as indirect Scope 3 emissions. That employee could decide to reduce their personal, direct emissions by riding a bicycle to work or carpooling, but since the employer does not have direct control over that decision, they are not held fully responsible for those emissions. The employer is, however, indirectly responsible for those emissions because they hired the employee, they chose the location of the workplace, and they more than likely subsidize driving alone to work by providing free parking.

From the perspective of the reporting entity, Scope 3 emissions are usually more difficult to count and more difficult to directly control. An extensive count of Scope 3 emissions can still be valuable information for a reporting entity, and in the case of a local government, reducing Scope 3 emissions should result in a reduction of the community-wide emissions.

Scoping assignments are standard practice in greenhouse gas accounting. As the ICLEI protocol mentions, reporting both Scope 1 and Scope 2 emissions as total emissions for a local government yields an emissions profile that accurately reflects the activities and energy decisions of that government's operations.

### ***List of Town Activities by Scope***

Among the activities under the Town of Cary's operational control, the following activities are classified as Scope 1 emissions:

- Town vehicle fleet
- C-Tran vehicle fleet
- Natural gas combustion in town buildings from gas purchased from PSNC Energy
- Fugitive N<sub>2</sub>O from the wastewater treatment processes
- Fugitive HFC refrigerants from the town vehicle fleet
- Fugitive HFC refrigerants from the transit vehicle fleet
- Fugitive HFC refrigerants from facilities' HVAC systems

Among the activities under the Town of Cary's operational control, the following activities are classified as Scope 2 emissions:

- Electricity use in all physical facilities from Progress Energy, Duke Energy and Town of Apex Energy including those from public works, transit, town hall, parks and recreation, emergency services, water treatment, and wastewater treatment
- Electricity use in Town-owned traffic signals
- Electricity use in streetlights paid for by the Town of Cary

# Appendix D: Departmental Energy Reports for 2010

---

## Administrative

|                             |                   |
|-----------------------------|-------------------|
| Total Emissions (MTCDE):    | 131               |
| Change from 2009:           | +5.5%             |
| Percent of Town Total:      | 0.3%              |
| <hr/>                       |                   |
| Estimated Energy Cost:      | \$20,661          |
| Activities with Energy Use: | Town Hall         |
| Number of Fleet Vehicles:   | 0                 |
| Average MPG:                | -                 |
| Shared Buildings:           | Town Hall A-- 30% |

The only energy consumption by the Administrative Department is from the office space in Town Hall A.

Due to the shared space, reduction opportunities are limited to efficiency improvements and energy reduction strategies at Town Hall.

Emissions Profile

Emissions Trend

## Engineering

|                             |                             |
|-----------------------------|-----------------------------|
| Total Emissions (MTCDE):    | 454                         |
| Change from 2009:           | +3.9%                       |
| Percent of Town Total:      | 1.0%                        |
| <hr/>                       |                             |
| Estimated Energy Cost:      | \$75,895                    |
| Activities with Energy Use: | Town Hall<br>Fleet Vehicles |
| Number of Fleet Vehicles:   | 25                          |
| Average MPG:                | 14.0                        |
| Shared Buildings:           | Town Hall B-- 30%           |

Among the most utilized vehicles in the 2010 Engineering Department fleet were a Chevrolet Suburban and Ford Excursion, each 10+ years old. Opportunities to downsize the fleet would save emissions. If full-sized SUVs are essential to daily activities, the hybrid Ford Escape offers a fuel efficiency rating more than 3 times higher than the 9.5 MPG recorded in 2010 by the Excursion.

Emissions Profile

Emissions Trend

## Finance

|                             |  |
|-----------------------------|--|
| Total Emissions (MTCDE):    | 341  |
| Change from 2009:           | +5.4%  |
| Percent of Town Total:      | 0.8%   |
| <hr/>                       |  |
| Estimated Energy Cost:      | \$63,352                                     |
| Activities with Energy Use: | Town Hall<br>James Jackson<br>Fleet Vehicles |
| Number of Fleet Vehicles:   | 18   |
| Average MPG:                | 13.3   |
| Shared Buildings:           | Town Hall A-- 30%<br>James Jackson 420-- 40% |

Energy use in office space generates the most emissions in the Finance Department, and gains in efficiency at the buildings would reduce totals. The 18-vehicle fleet consists entirely of mid-sized pickups that receive less than 15 miles per gallon, yielding opportunity for more efficient replacements.

## Inspections and Permits

|                             |                             |
|-----------------------------|-----------------------------|
| Total Emissions (MTCDE):    | 329                         |
| Change from 2009:           | +5.7%                       |
| Percent of Town Total:      | 0.7%                        |
| Estimated Energy Cost:      | \$57,823                    |
| Activities with Energy Use: | Town Hall<br>Fleet Vehicles |
| Number of Fleet Vehicles:   | 33                          |
| Average MPG:                | 15.1                        |
| Shared Buildings:           | Town Hall B-- 16%           |

With emissions split between energy use in space at Town Hall and an expanding vehicle fleet, the Inspections and Permits Department can reduce their emissions most easily by right-sizing the 33 vehicle fleet it operates. Purchases in 2010 of the Toyota Prius and Ford Escape hybrids are a step in the right direction and should be repeated in future vehicle replacements.

## Planning

|                             |                   |
|-----------------------------|-------------------|
| Total Emissions (MTCDE):    | 208               |
| Change from 2009:           | +3.3%             |
| Percent of Town Total:      | 0.5%              |
| <hr/>                       |                   |
| Estimated Energy Cost:      | \$33,808          |
| Activities with Energy Use: | Town Hall         |
| Number of Fleet Vehicles:   | 7                 |
| Average MPG:                | 12.6              |
| Shared Buildings:           | Town Hall B-- 14% |

With an available fleet of only 7 vehicles, the majority of the emissions from activities of the Planning Department are the result of shared office space in Town Hall B.

Even so, the 7 vehicle fleet consists mainly of oversized pickups and SUVs. The addition of two midsize pickups in 2010 is a step in the right direction, but more opportunities exist.

| Number of Fleet Vehicles:   | 136   |
| Average MPG:                | 11.3  |
| Shared Buildings:           | Town Hall C-- 85%                           |

The Police Department fleet has grown considerably in size since 2005, according to fleet records from Public Works. Considering the large share of mobile emissions, the introduction of alternative fuels such as E85 or hybrid vehicles such as the Ford Escape can significantly decrease the departmental totals.

Emissions Profile

Emissions Trend

With only 2 vehicles, the majority of energy consumption by the Legislative Department is from the office space in Town Hall C. Thus, the largest reduction opportunities exist in efficiency improvements at Town Hall C, but there also is opportunity to improve the fuel efficiency of the 2-vehicle fleet either with passenger cars or the hybrid Ford Escape.

## Transit

|                             |                           |
|-----------------------------|---------------------------|
| Total Emissions (MTCDE):    | 923.1                     |
| Change from 2009:           | +15.3%                    |
| Percent of Town Total:      | 2.1%                      |
| Estimated Energy Cost:      | \$197,944                 |
| Activities with Energy Use: | C-Tran Vehicles           |
| Number of Fleet Vehicles:   | 59                        |
| Average MPG:                | 10.6                      |
| Shared Buildings:           | None-- contracted service |

Emissions Profile

Because fuel data within the the Transit fleet has been poorly recorded throughout this study period, there is limited insight into these activities. An annual vehicle count parallels the steadily increasing emissions trend.

| Year | Count |
|------|-------|
| 2005 | 20    |
| 2006 | 29    |
| 2007 | 27    |
| 2008 | 28    |
| 2009 | 36    |
| 2010 | 59    |
